Robustness of capturing behavioural and sexual lifestyle data for a complex clinical study using internet-based computer assisted self-interview

Sexual behaviour and vaginal practices impact on vaginal patholgy, but accurately capturing such data for multi-site clinical studies is logistically difficult. Computer assisted self-interviews (CASI), are useful for capturing sensitive information for community surveys but require programming expertise or expensive software. We piloted an open-source software designed internet-based CASI, using previously validated questions for the “eSTI” consortium: Investigating the Polymicrobial nature of Sexually transmitted infection (STI) syndromes (PolySTI) study, a multi-site clinical study on the vaginal microbiome. Common correlates of bacterial vaginosis (BV), a common vaginal dysbiosis, were examined. Smoking and vaginal douching are associated with BV\(^2\); White ethnicity and combined hormonal contraceptives are inversely related to BV\(^4,3\).

Methods
Women attending sexual and reproductive health clinics across four clinical sites in and around London, UK were recruited to the PolySTI, where data were collected using internet-based CASI. The CASI question-structure was constructed from the third UK National Survey of Sexual Attitudes and Lifestyles\(^5\) using the LimeSurvey\(^6\) open-source software, consisting of 71 questions, and was delivered via a responsive algorithm. These covered demographics, sexual behaviour, vaginal practices, contraception, and life-time smoking history. Patients could decline questions and the CASI was delivered to participants online. BV status was determined by Nugent scores from Gram-stained lateral vaginal swab smears.

Results

- 155 women had available Nugent scores.
- Mean time to completing CASI was just over 5 minutes (Range: 1 minute 52 seconds-11 minutes 10 seconds 95% CI ± 17 seconds).
- There were no missing data.
- Most participants declined to answer “number of one-off partners” (14 participants, 9%).
- White ethnicity and combined hormonal contraceptives (CHC) were inversely related with BV (Odds ratios (OR): 0.33 [95%CI: 0.16-0.67] and 0.41 [0.17-0.97] respectively)
- Lifetime smoking of >1 pack-years and regular vaginal douching were directly related with BV (OR: 2.56 [1.21-5.41] and 2.03 [1.01-4.09] respectively).
- Nearly 50% of women reported daily vaginal douching and >90% reported using feminine care products in the preceding month.

Conclusion
The CASI delivered a complete dataset, the findings from which were consistent with published associations of BV, demonstrating robustness. Web-based CASI is an efficient method of collecting sensitive sexual and behavioural data within a complex clinical study, from patients recruited in busy clinical settings, and can be developed using open-source questionnaire software without the need for coding expertise. This is data from women only. Men may respond differently; future work is planned to compare CASI with NIH Chronic Prostatitis Symptom Index scores in men with prostatitis.
